ENV 790.30 - Time Series Analysis for Energy Data | Spring 2022

Assignment 4 - Due date 02/17/22

Kristen Pulley

Directions

You should open the .rmd file corresponding to this assignment on RStudio. The file is available on our class repository on Github. And to do so you will need to fork our repository and link it to your RStudio.

Once you have the project open the first thing you will do is change "Student Name" on line 3 with your name. Then you will start working through the assignment by **creating code and output** that answer each question. Be sure to use this assignment document. Your report should contain the answer to each question and any plots/tables you obtained (when applicable).

When you have completed the assignment, **Knit** the text and code into a single PDF file. Rename the pdf file such that it includes your first and last name (e.g., "LuanaLima_TSA_A04_Sp21.Rmd"). Submit this pdf using Sakai.

R packages needed for this assignment: "xlsx" or "readxl", "ggplot2", "forecast","tseries", and "Kendall". Install these packages, if you haven't done yet. Do not forget to load them before running your script, since they are NOT default packages.\

Questions

Consider the same data you used for A3 from the spreadsheet "Table_10.1_Renewable_Energy_Production_and_Consumpti
The data comes from the US Energy Information and Administration and corresponds to the January 2021 Monthly Energy Review. For this assignment you will work only with the column "Total Renewable Energy Production".

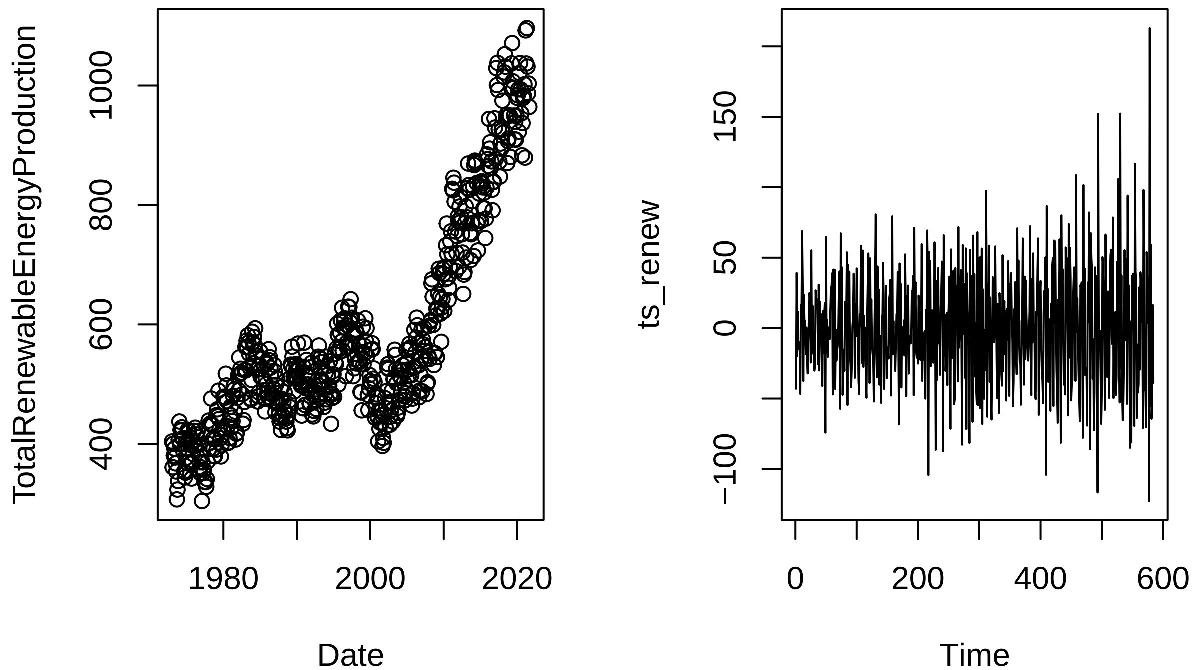
Stochastic Trend and Stationarity Tests

Q1

Difference the "Total Renewable Energy Production" series using function diff(). Function diff() is from package base and take three main arguments: * *x* vector containing values to be differenced; * *lag* integer indicating with lag to use; * *differences* integer indicating how many times series should be differenced.

Try differencing at lag 1 only once, i.e., make `lag=1` and `differences=1`. Plot the differenced series Do the series still seem to have trend?

The series does not seem to have the trend.



Q2

Now let's compare the differenced series with the detrended series you calculated on A3. In other words, for the "Total Renewable Energy Production" compare the differenced series from Q1 with the series you detrended in A3 using linear regression. (Hint: Just copy and paste part of your code for A3)

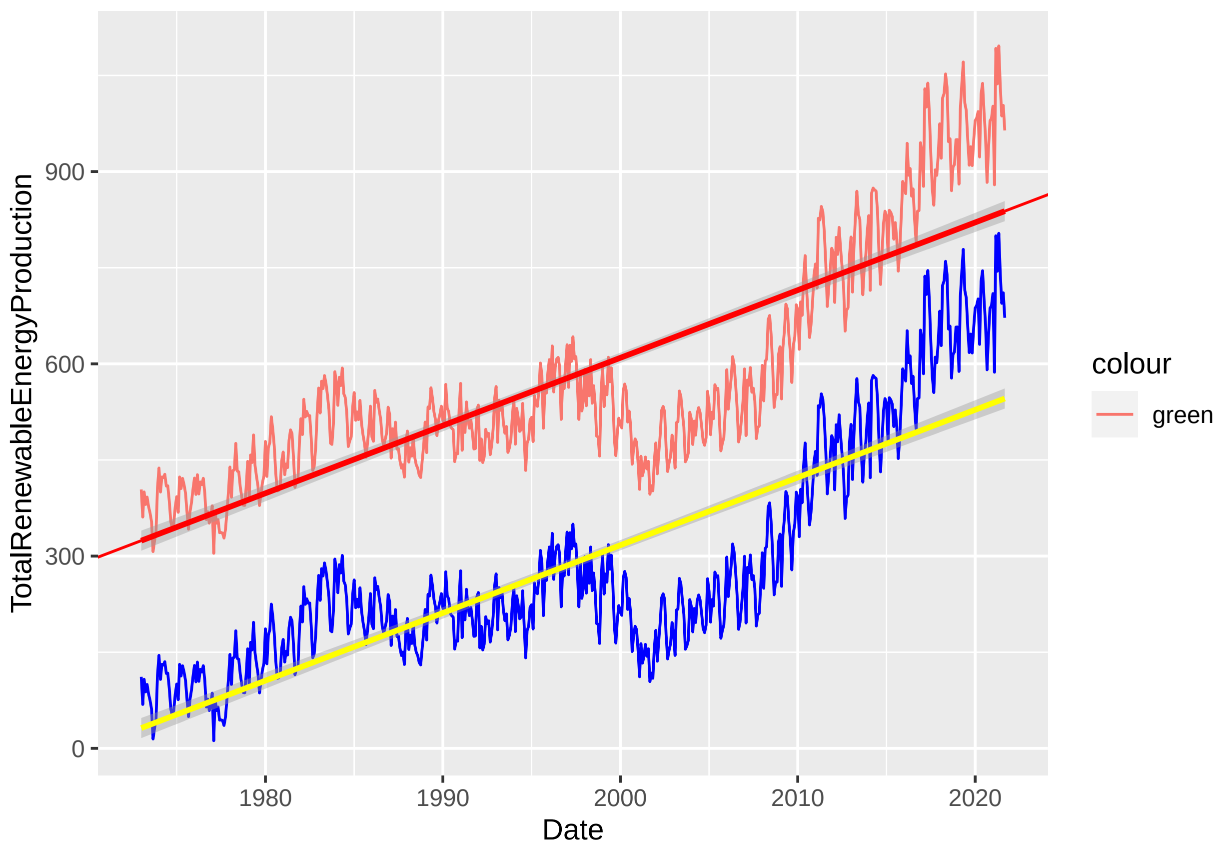
Copy and paste part of your code for A3 where you compute regression for Total Energy Production and the detrended Total Energy Production

```
##
## Call:
## lm(formula = TotalRenewableEnergyProduction ~ Date, data = energy.df)
##
## Residuals:
##      Min       1Q   Median       3Q      Max
## -230.504  -57.854    5.575   62.062  261.374
##
## Coefficients:
##              Estimate Std. Error t value Pr(>|t|)
## (Intercept) 2.924e+02  8.755e+00    33.4   <2e-16 ***
## Date        3.348e-07  9.024e-09    37.1   <2e-16 ***
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 96.94 on 583 degrees of freedom
```

```
## Multiple R-squared:  0.7025, Adjusted R-squared:  0.702
## F-statistic:  1376 on 1 and 583 DF,  p-value: < 2.2e-16

## Warning in energy.df[, 2] - (beta0 + beta1 * t): longer object length is not a
## multiple of shorter object length

## `geom_smooth()` using formula 'y ~ x'
## `geom_smooth()` using formula 'y ~ x'
```

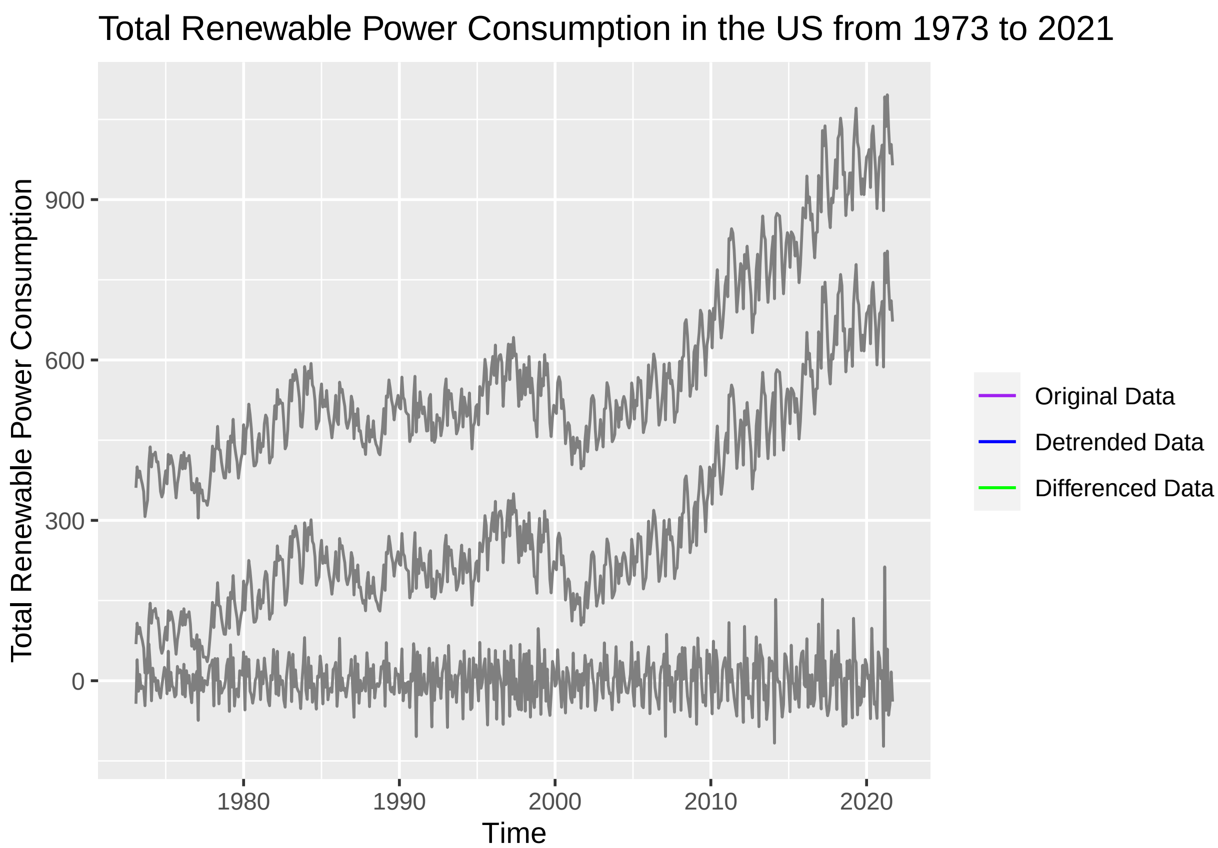


Q3

Create a data frame with 4 columns: month, original series, detrended by Regression Series and differenced series. Make sure you properly name all columns. Also note that the differenced series will have only 584 rows because you loose the first observation when differencing. Therefore, you need to remove the first observations for the original series and the detrended by regression series to build the new data frame.

Q4

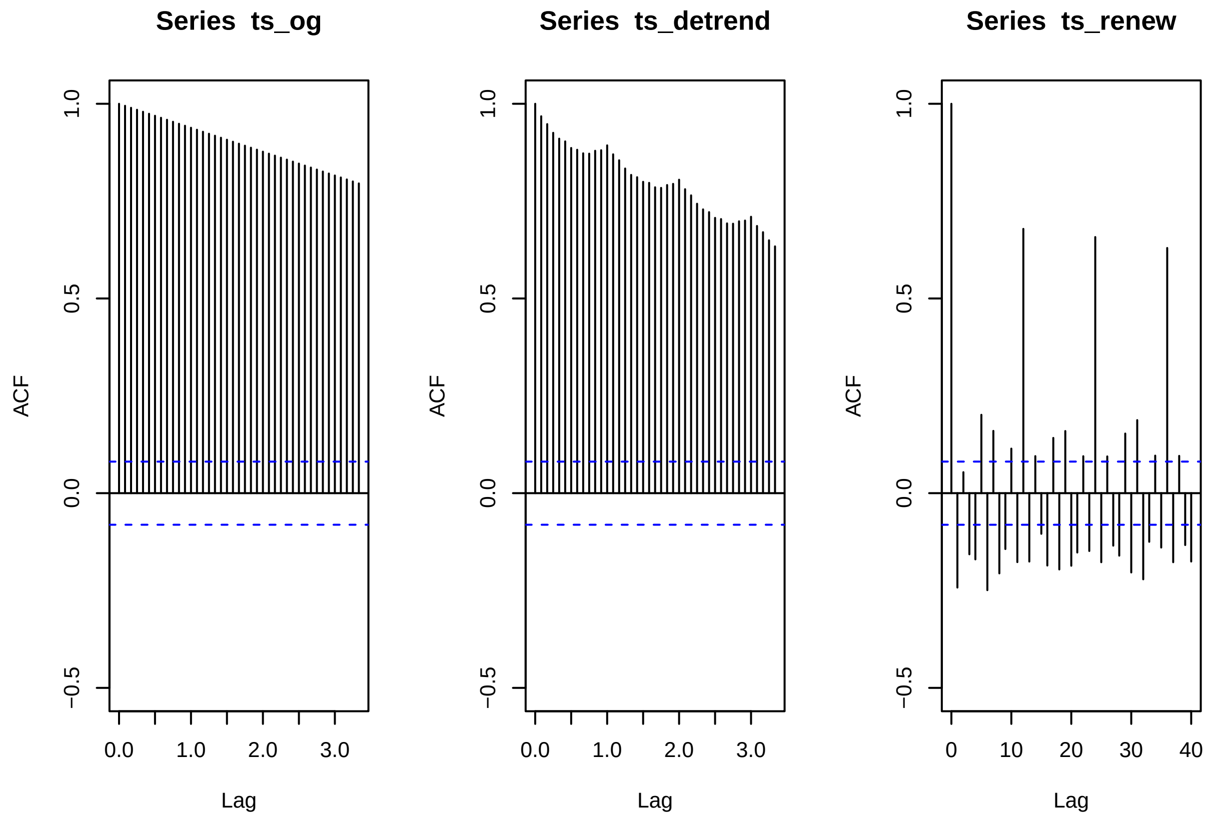
Using ggplot() create a line plot that shows the three series together. Make sure you add a legend to the plot.



Q5

Plot the ACF for the three series and compare the plots. Add the argument `ylim=c(-0.5,1)` to the Acf() function to make sure all three y axis have the same limits. Which method do you think was more efficient in eliminating the trend? The linear regression or differencing?

Based on the ACFs, the differencing seems to have eliminated the trend most efficiently.



Q6

Compute the Seasonal Mann-Kendall and ADF Test for the original "Total Renewable Energy Production" series. Ask R to print the results. Interpret the results for both test. Whats the conclusion from the Seasonal Mann Kendall test? What's the conclusion for the ADF test? Do they match what you observed in Q2? Recall that having a unit root means the series has a stochastic trend. And when a series has stochastic trend we need to use a different procedure to remove the trend.

```
## tau = 1, 2-sided pvalue =< 2.22e-16
```

```
## Warning in adf.test(ts_og): p-value smaller than printed p-value
```

```
##
##  Augmented Dickey-Fuller Test
##
## data:  ts_og
## Dickey-Fuller = -8.778, Lag order = 8, p-value = 0.01
## alternative hypothesis: stationary
```

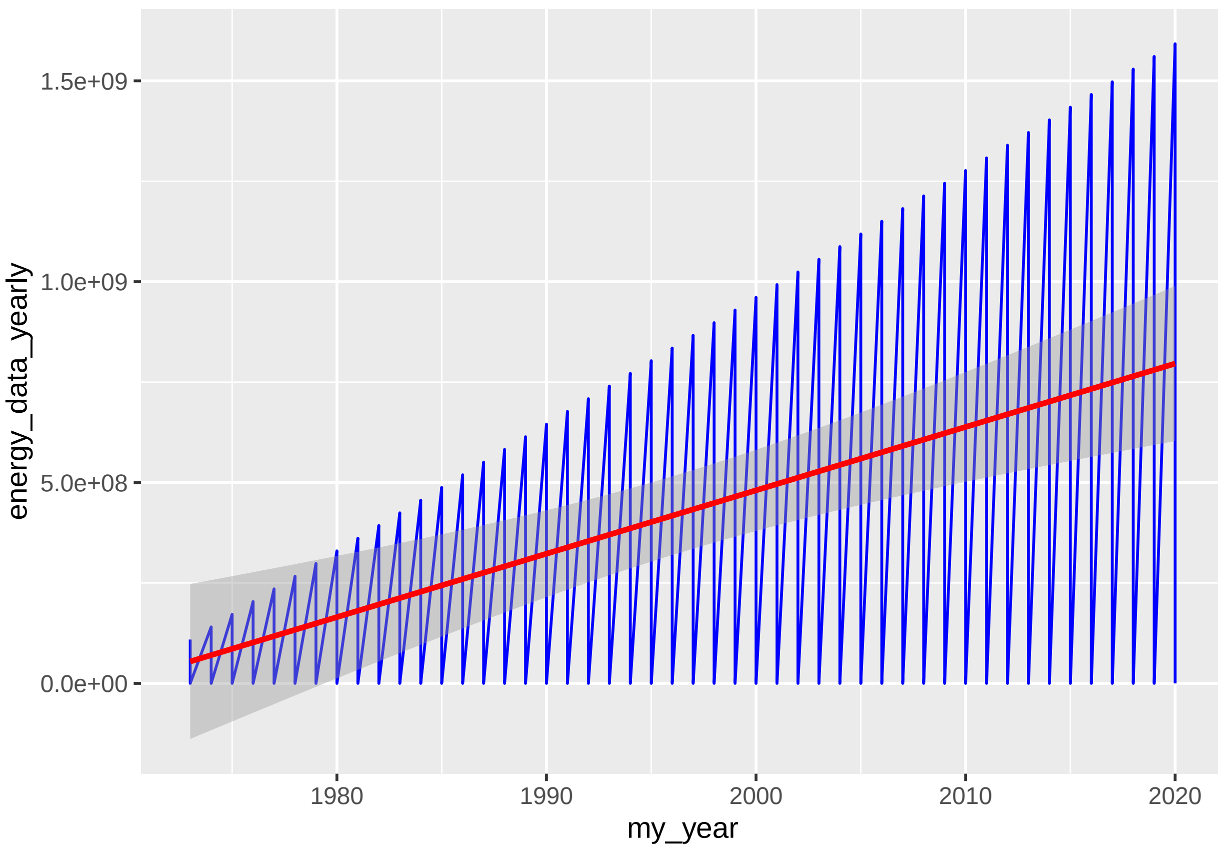
The results of the Seasonal Mann Kendall test indicates a p-value<0.01. The p-value is below the alpha value of 0.05, meaning we can reject the null hypothesis. Therefore, there is sufficient evidence to suggest a trend is present in the data.

The results of the ADF test indicates a p-value<0.01. The p-value is below the alpha value of 0.05, meaning we can reject the null hypothesis. Therefore, there is sufficient evidence to suggest a trend is present in the data.

The results of these tests indicate that the series have a stochastic trend that must be removed through a different process. This matches my observation in Q2, which show a clear trend in the series. ### Q7

Aggregate the original "Total Renewable Energy Production" series by year. You can use the same procedure we used in class. Store series in a matrix where rows represent months and columns represent years. And then take the columns mean using function colMeans(). Recall the goal is the remove the seasonal variation from the series to check for trend.

```
## 'geom_smooth()' using formula 'y ~ x'
```



Q8

Apply the Mann Kendal, Spearman correlation rank test and ADF. Are the results from the test in agreement with the test results for the non-aggregated series, i.e., results for Q6?

```
###Seasonal MannKendall()

SMKtest <- SeasonalMannKendall(ts_og2)
print("Results for Seasonal Mann Kendall /n")
```

```
## [1] "Results for Seasonal Mann Kendall /n"
```

```
print(summary(SMKtest))
```

```
## Score =  -57690 , Var(Score) = 170090176
## denominator =  662976
## tau = -0.087, 2-sided pvalue =9.7138e-06
## NULL
```

```r
#Use yearly date to run Mann Kendall
print("Results of Mann Kendall on average yearly series")
```

```
## [1] "Results of Mann Kendall on average yearly series"
```

```r
print(summary(MannKendall(energy_data_yearly)))
```

```
## Score =  -360 , Var(Score) = 99813.34
## denominator =  4560
## tau = -0.0789, 2-sided pvalue =0.25582
## NULL
```

```r
### Spearman Correlation test

#Deterministic trend with Spearman Correlation Test
#print("Results from Spearman Correlation")
#sp_rho=cor(energy_data_yearly,my_year[1:576,],method="spearman")
#print(sp_rho)

#with cor.test you can get test statistics
#sp_rho=cor.test(energy_data_yearly,my_year,method="spearman")
#print(sp_rho)

### Augmented Dickey Fuller (ADF)

#Null hypothesis is that data has a unit root
#print("Results for ADF test/n")
#print(adf.test(ts_og2,alternative = "stationary"))

#Now let's try the yearly data
#print("Results for ADF test on yearly data/n")
#print(adf.test(energy_data_yearly, alternative = "stationary"))
```
